

### **REMARKS**

In view of the above amendments and the following remarks, reconsideration of the rejections contained in the Office Action of August 14, 2008 is respectfully requested.

By this amendment claims 1-2, and 4-10 have been amended and claims 11-20 have been added. Claims 1-20 are now pending in the application. No new matter has been added by these amendments.

The entire specification has been reviewed and revised. Due to the number of revisions, the amendments to the specification have been incorporated into the attached substitute specification. For the Examiner's benefit, a marked-up copy of the specification and abstract indicating the changes made thereto is also enclosed. No new matter has been added by these revisions. Entry of the substitute specification is thus respectfully requested.

Applicants thank the Examiner for consideration of the application, including the information disclosure statement, and the comments of the August 14, 2008 Office Action. In that Office Action, the Examiner indicated that claims 4-8 would be allowable if rewritten in independent form. Claim 5 has been rewritten in independent form. Claim 5 contains minor grammatical and idiomatic corrections, and corrections to problems similar to those noted by the Examiner on page 2, item 2 of the Office Action. Claims 4, and 6-8 also contain corrections to problems similar to those noted by the Examiner on page 2, item 2 of the Office Action. Because the scope of claims 4-8 is virtually identical to that indicated allowable, allowance is believed to be in order. New claims 12, 14, and 18 depend directly or indirectly from claim 5, and are thus allowable for at least the same reasons as claim 5.

On page 2 of the Office Action, the Examiner alleges that claims 9 and 10 are indefinite.

Those claims have been amended to overcome the rejection, to put claim 9 in independent form, and to include minor grammatical and idiomatic corrections. Because no prior art was applied and the indefiniteness rejection is believed to be overcome, allowance of claims 9-10 is believed to be in order. New claims 15 and 16 depend directly or indirectly from claim 9, and are thus allowable for at least the same reasons as claim 9.

Beginning on page 2 of the Office Action, the Examiner alleges that claims 1 and 3 are anticipated by Rainey (US 6,969,809) under 35 U.S.C. § 102(b). As an initial matter, Rainey (US 6,969,809) was not “patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of the application for patent in the United States” as required by 35 U.S.C. § 102(b).

“A claim is anticipated only if each and every element as set forth in the claim is found, either expressly or inherently described, in a single prior art reference.” MPEP 2131; *Verdegaal Bros. v. Union Oil Co. of California*, 814 F.2d 628, 631 (Fed. Cir. 1987). Before the present amendment, claim 1 recited in part: “inserting at least one of the first washer and the second washer *into the first hole...*” (emphasis added). As seen in Figure 6 of Rainey, the washers 80 and 90 of Rainey are ordinary washers that are not inserted into hole 51, or any other hole. As illustrated in Figure 7 of Rainey, bolt 43 is inserted into and completely fills hole 51; washers 80 and 90 do not occupy any portion of hole 51. Because Rainey does not disclose each element of unamended claim 1, Applicants believe that the rejection of claims 1 and 3 is improper.

In an effort to advance prosecution, and without agreeing to the propriety of the Examiner’s rejection, claim 1 has been amended to more clearly require that a portion of at least one of the washers is disposed within the first hole. In particular, claim 1 now requires that the

first or second washer comprise a first insertion part extending into the first hole. Because Rainey does not disclose nor render obvious every limitation of claim 1, allowance is respectfully requested. Claims 2-4, 11, 13, 17, 19, and 20 depend directly or indirectly from claim 1, and are thus allowable for at least the same reasons as claim 1.

With respect to claim 3, in addition to being allowable for depending from claim 1, Applicants submit that this claim has additional limitations not anticipated by Rainey as asserted in the Office Action, nor rendered obvious by the prior art. Claim 3 requires “the first washer...attached to the first face of the substrate,” and “the second washer...attached to the second face of the substrate.” At least washer 80 of Rainey is not attached to either surface of the substrate, as illustrated in Figure 7.

On page 3 of the Office Action, the Examiner alleges that claim 2 would have been obvious in view of Rainey. Applicants respectfully traverse this rejection; in addition to being allowable for depending from claim 1, claim 2 includes further limitations which are not anticipated nor rendered obvious by the prior art.

“[R]ejections on obviousness cannot be sustained by mere conclusory statements; instead, there must be some articulated reasoning with some rational underpinning to support the legal conclusion of obviousness.” KSR, 550 U.S. at \_\_\_, 82 USPQ2d 1385, 1396 (2007); MPEP 2141. Applicants note that Rainey does not disclose “a first insertion part,” “a second insertion part,” “the first insertion part [being] inserted into the first hole,” nor the “press-fitted to an internal periphery of the first insertion part,” as recited in claim 2. The Examiner has not cited prior art which discloses any of these features of claim 2. The Examiner has not alleged any teaching, suggestion, or motivation to add any of these features to the apparatus of Rainey. The

Examiner has not cited any reference which teaches or suggests the use of press-fitting in strain sensors. It is respectfully asserted that the Examiner has not established a *prima facie* case of obviousness; withdrawal of this rejection is requested.

In view of the foregoing amendments and remarks, inasmuch as all of the outstanding issues have been addressed, Applicants respectfully submit that the present application is in complete condition for issuance of a formal Notice of Allowance, and action to such effect is earnestly solicited.

Should any issues remain after consideration of the within response, however, the Examiner is invited to telephone the undersigned at his convenience. If any fee beyond that submitted herewith, or extension of time is required to obtain entry of this Amendment, the undersigned hereby petitions the Commissioner to grant any necessary time extension and authorizes charging Deposit Account 23-0975 for any such fee not submitted herewith.

Respectfully submitted,

Yasunori MATSUKAWA et al.

## **Description**

### **STRAIN SENSOR**

This application is a U.S. national phase application of PCT  
5 International Application PCT/JP2004/002071.

### **TECHNICAL FIELD**

The present invention relates to a strain sensor for detecting strain caused by  
external forces, such as human weight and vehicle weight, using a strain-detecting  
element provided on a sensor substrate.

10

### **BACKGROUND ART**

A conventional strain sensor is disclosed in Japanese Utility Model  
Unexamined Publication No. H5-57605, and is described below with reference to  
the drawings.

15

Fig. 8 is a perspective view of the conventional strain sensor, and Fig. 9 is a  
side sectional view illustrating the conventional strain sensor fixed to its detection  
target. Metal sensor substrate 1 has fixing holes 2 and 3. Strain-detecting element  
4, consisting of a strain gauge, is disposed on the top face of sensor substrate 1.  
Strain-detecting element 4 includes element portion 5, and lead 6 electrically coupled  
20 to element portion 5 and protruding outward.

20

The operation of the conventional strain sensor as configured above is  
described next with reference to Fig. 9. A pair of internal threads 7 is provided in  
advance on detection target 8. Sensor substrate 1 is fixed to detection target 8 by  
screwing external threads 9 into internal threads 7 with sensor substrate 1  
25 therebetween. The inner diameter of fixing holes 2 and 3 is slightly greater than the  
outer diameter of internal threads 7. This is to ensure the reliable fixing of sensor  
substrate 1 onto detection target 8, considering variations in the pitch of internal

threads 7 provided on detection target 8. In this state, when an external force is applied to detection target 8, detection target 8 distorts, and sensor substrate 1 deforms in response to this distortion. The deformation of sensor substrate 1 is output from lead 6 as a change in voltage caused by a change in resistance of strain-detecting element 4 provided on the top face of sensor substrate 1. Accordingly, the external force applied to detection target 8 is detectable.

However, in the above conventional structure, a twisting force acts on external threads 9 when sensor substrate 1 is fixed to detection target 8 by screwing external threads 9 into internal threads 7. This twisting force produces internal stress in sensor substrate 1. As a result, strain-detecting element 4 distorts, and an output signal is generated even when no external force is applied to sensor substrate 1. Consequently, output signals from the strain sensor become inaccurate.

## SUMMARY OF THE INVENTION

In the strain sensor of the present invention, a fixing member is composed of an upper washer and a lower washer. By sandwiching and holding a sensor substrate with ~~these~~the upper washer and ~~the~~ lower washer, the fixing member is fixed onto the sensor substrate. A strain-detecting element is disposed on the sensor substrate. The strain sensor having this structure is thus fixed onto a detection target by means of the fixing member.

## BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a top view of a strain sensor in accordance with an exemplary embodiment of the present invention.

Fig. 2 is a side sectional view of the strain sensor shown in Fig. 1.

Fig. 3 is an exploded perspective view illustrating the state before fixing a first fixing member to a sensor substrate in the strain sensor shown in Fig. 1.

Fig. 4 is a top view of the sensor substrate in the strain sensor shown in Fig. 1.

Fig. 5 is a side sectional view illustrating an operation state of the strain sensor shown in Fig. 1.

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Fig. 1 is a top view of a strain sensor in an exemplary embodiment of the present invention. Fig. 2 is a side sectional view of the strain sensor, and Fig. 3 is an exploded perspective view illustrating the state before fixing a first fixing member to a sensor substrate in the strain sensor. Fig. 4 is a top view of the sensor substrate in the strain sensor.

Sensor substrate (hereinafter “substrate”) 11 has first fixing hole (hereinafter “hole”) 12 passing through from the top face (first face) to the bottom face (second face opposing the first face) at a first-end side. At the approximate center, substrate 11 also has second fixing hole (hereinafter “hole”) 13 passing through from the top face to the bottom face. ~~Still more~~Furthermore, substrate 11 has detection hole (hereinafter “hole”) 14 passing through from the top face to the bottom face at the approximate center between hole 12 and hole 13. Power electrode 15 is disposed at a second-end side of substrate 11. Power electrode 15 is electrically coupled to a first end of first strain-detecting element (hereinafter “element”) 16 and a first end of

second strain-detecting element (hereinafter “element”) 17 via circuit pattern 18. A second end of element 16 is electrically coupled to first output electrode 19. A second end of element 17 is electrically coupled to second output electrode 20 and a first end of third strain-detecting element 21 (hereinafter “element”). A second end  
 5 of element 21 is electrically coupled to GND electrode 22.

Fourth strain-detecting element (hereinafter “element”) 23 is disposed on the top face of substrate 11. A first end of element 23 is electrically coupled to the second end of element 16 and first output electrode 19. A second end of element 23 is electrically coupled to GND electrode 22. In this way, elements 16, 17, 21,  
 10 and 23; power electrode 15; output electrodes 19 and 20; GND electrode 22; and circuit pattern 18 configure a bridge circuit.

IC 24 is disposed on the top face of substrate 11 at the second-end side. IC 24 amplifies differential voltage between the voltage of first output electrode 19 and that of second output electrode 20, and outputs it outside through connector 25  
 15 provided at the second-end side of substrate 11.

External power electrode 26 is also disposed on the top face of substrate 11 at the second-end side. External power electrode 26 is electrically coupled to power electrode 15. External GND electrode 27 is also disposed on the top face of substrate 11, and external GND electrode 27 is electrically coupled to GND electrode  
 20 22.

As shown in Fig. 3, first fixing member (hereinafter “member”) 28 is composed of first upper washer (hereinafter “washer”) 29 made of metal and first lower washer (hereinafter “washer”) 30 made of metal. Washer 29 contacts the top face of substrate 11, and washer 30 contacts the bottom face of substrate 11. Washer  
 25 29 includes round contact head 31 touching the top face of substrate 11 and insertion part 32 inserted into hole 12 on substrate 11. In the same way as washer 29, washer 30 also has round contact head 33 touching the bottom face of substrate 11 and

insertion part 34 inserted into hole 12. Member 28 is fixed onto substrate 11 by press-fitting the outer periphery of insertion part 32 of washer 29 into inner periphery 34A of insertion part 34 of washer 30.

Insertion part 34 of washer 30 is inserted into fixing hole 12, fitting with a  
 5 clearance [[to]]in hole 12. When the outer periphery of insertion part 32 is press-fitted to the inner periphery of insertion part 34 in this state, washer 29 and washer 30 sandwich and hold substrate 11 without applying an internal stress to substrate 11. With this structure, member 28 is fixed onto substrate 11 without applying an internal stress to substrate 11. In addition, ~~there is no chance that~~  
 10 member 28 ~~comes off from~~holds securely to substrate 11.

Second fixing member (hereinafter “member”) 35 is also composed of second upper washer (hereinafter “washer”) 36 made of metal and second lower washer (hereinafter “washer”) 37 made of metal, in the same configuration as member 28. Detection member (hereinafter “member”) 38 is composed of upper  
 15 metal washer (hereinafter “washer”) 39 of detecting portion and lower metal washer (hereinafter “washer”) 40 of detecting portion. Member 28 and member 35 are fixed to a base (not illustrated) of a measurement target via holes 51 and 53. Member 38 is fixed to a part (not illustrated) of the measurement target where strain may occur via hole 52 so as to ~~receive~~measure a strain force [[of]]acting on the  
 20 measurement target.

In the present exemplary embodiment, an external stress is applied to end 38A of member 38 which contacts substrate 11. A reaction force acts between end 28A of member 28 which contacts substrate 11 and end 35A of member 35 which contacts substrate 11.

25 Next, an assembly method of the strain sensor as configured above is described.

First, holes 12, 13, and 14 are formed by press working on a metal base material (not illustrated) prepared in advance. Next, glass paste (not illustrated) is printed on the top face of the base material (not illustrated), and then the base material is fired at about 850 °C for about 45 minutes to form substrate 11.

5       Next, metal-glazed carbon paste is printed on the top face of substrate 11, and fired at about 850 °C for about 45 minutes. Elements 16, 17, 21, and 23 are formed on the top face of substrate 11. Then, silver paste is printed on positions where power electrode 15, first output electrode 19, second output electrode 20, GND electrode 22, and circuit pattern 18 are to be provided, and fired at about 850  
10   °C for about 45 minutes. In this way, power electrode 15, first output electrode 19, second output electrode 20, GND electrode 22, and circuit pattern 18 are formed. IC24 is then mounted on the top face of substrate 11.

Next, insertion part 34 of washer 30 is inserted into hole 12 from the bottom, and then insertion part 32 of washer 29 is inserted into hole 12 from the top. The  
15   top face of contact head 33 of washer 30 is attached to the bottom face of substrate 11, and the bottom face of contact head 31 of washer 29 is attached to the top face of substrate 11. Here, member 28 is fixed to substrate 11 by press-fitting the outer periphery of insertion part 32 into the inner periphery of insertion part 34.

In this way, member 28 is fixed to substrate 11 by sandwiching and holding  
20   substrate 11 with washer 29 and washer 30. In this case, a force perpendicular to the thickness direction of substrate 11, generated by sandwiching and holding substrate 11 with washer 29 and washer 30, fixes member 28 onto substrate 11. Accordingly, no internal stress caused by twisting around hole 12 on substrate 11 is produced. Likewise, no continuous stress is applied to element 21 disposed near  
25   hole 12. ~~[[The]]Accordingly, a more accurate output signal from the strain sensor thus becomes accurate is achieved.~~

Next, in the same way as member 28, member 35 composed of washer 36 and washer 37 is fixed near hole 13 on substrate 11. Lastly, member 38 composed of washer 39 and washer 40 is fixed near hole 14 on substrate 11.

5 The operation of the strain sensor as configured and assembled above is described next with reference to Fig. 5. Fig. 5 is a side sectional view illustrating the operation state of strain sensor in the exemplary embodiment.

When an external force is applied to member 38 from the top as indicated by an arrow in Fig. 5, substrate 11 deforms. At this time, the external force is applied to end 38A of member 38. On the other hand, a reaction force acts to end 28A of member 28 and end 35A of member 35. A tensile stress is also applied to elements 16 and 21, increasing resistance of elements 16 and 21. On the other hand, a compression stress is applied to elements 17 and 23, reducing resistance of elements 17 and 23. Since a bridge circuit is formed among elements 16, 17, 21, and 23, IC 24 outputs a potential difference between first output electrode 19 and second output electrode 20 as the differential voltage through connector 25.

Here, the reaction force applied to member 28 includes a vector which rotates member 28 circumferentially, and thus it is conceivable that member 28 is rotated. However, as shown in Fig. 3, washer 29 has contact head 31 which touches the top face of substrate 11. In addition, washer 30 has contact head 33 which touches the bottom face of substrate 11. Still more, these contact heads 31 and 33 are round. Accordingly, even though washer 29 rotates on the top face and washer 30 rotates on the bottom face of substrate 11 respectively in a circumferential direction, the positions of contact heads against substrate 11 do not deviate lengthwise on substrate 11 with respect to washers 29 and 30. Therefore, a bending stress applied to element 21 provided near member 28 does not change, allowing the strain sensor to maintain stable output characteristic.

In this structure, insertion part 34 of washer 30 is inserted into hole 12 on substrate 11 from the bottom, and then insertion part 32 of washer 29 is inserted into hole 12 from the top. Then, the top face of contact head 33 of washer 30 is attached to the bottom face of substrate 11. The bottom face of contact head 31 of washer 29 is attached to the top face of substrate 11. At this point, the outer periphery of insertion part 32 is press-fitted to the inner periphery of insertion part 34 so as to fix member 28 onto substrate 11.

~~Contrary~~Alternatively, insertion part 32 of washer 29 may be inserted into hole 12 from the bottom, and then insertion part 34 of washer 30 may be inserted into hole 12 from the top. In this case, the top face of contact head 31 of washer 29 is touched to the bottom face of substrate 11, and the bottom face of contact head 33 of washer 30 is touched to the top face of substrate 11. In this case, the inner periphery of insertion part 34 is press-fitted into the outer periphery of insertion part 32 so as to fix member 28 onto substrate 11. With this structure, the same effect as the structure previously described is achievable. The same applies to member 35 and member 38.

Next, another strain sensor in the exemplary embodiment of the present invention is described. Fig. 6 is a side sectional view of another strain sensor in the exemplary embodiment of the present invention. Fig. 7 is an exploded perspective view of the strain sensor before fixing a first fixing member onto a sensor substrate.

In this structure, the first fixing member (hereinafter “member”) 41 is composed of first upper washer (hereinafter “washer”) 29 made of metal and first lower washer (hereinafter “washer”) 42 made of metal. Washer 29 contacts the top face of substrate 11, and washer 42 contacts the bottom face of substrate 11. The top face of washer 42 contacts the bottom face of substrate 11. Hole 43 passing through from the top face to the bottom face is formed in washer 42. Member 41 composed of washer 29 and washer 42 is

fixed onto substrate 11 by press-fitting insertion part 32 of washer 29 into hole 43. In the same way as for member 41, second fixing member (hereinafter “member”) 44 is composed of second upper washer (hereinafter “washer”) 36 made of metal and second lower washer (hereinafter “washer”) 45 made of metal. Detection member (hereinafter “member”) 46 is also composed of upper metal washer (hereinafter “washer”) 39 of detecting portion and lower metal washer (hereinafter “washer”) 47 of detecting portion. Washers 36 and 39 have the same structure as washer 29, and washers 45 and 47 have the same structure as washer 42. First fixing member 41 and member 44 are fixed to a base (not illustrated) of the measurement target via holes 61 and 63. Member 46 is fixed via hole 62 to a portion (not illustrated) of the measurement target where strain is generated.

In this structure, insertion part 32 is provided on washer 29 and hole 43 is formed on washer 42; and insertion part 32 is press-fitted into hole 43. In this way, member 41 is fixed onto substrate 11. Accordingly, the entire washer 42 is press-fitted with washer 29. In addition, insertion part 32 of washer 29 can be thickened, contributing to improved strength of member 41.

In the structure of the strain sensor as configured above, first and second fixing members 41 and 44, and washers 29, 36, and 39 of member 46 have insertion parts. Holes are formed on washers 42, 45, and 47 of members 41, 44, and 46. The insertion parts of washers 29, 36, and 39 are respectively press-fitted into holes on washers 42, 45, and 47. Accordingly, members 41, 44, and 46 are fixed onto substrate 11. ~~Conversely~~Alternatively, insertion parts may be provided on lower washers 42, 45, and 47, and holes may be provided on upper washers 29, 36, and 39. In this case, the insertion parts of washers 42, 45, and 47 are press-fitted into holes on washers 29, 36, and 39 so as to fix members 41, 44, and 46 onto substrate 11. This structure also demonstrates the same effect.

The operation of the strain sensor as configured and assembled above is described next with reference to Fig. 5. Fig. 5 is a side sectional view illustrating the operation state of strain sensor in the exemplary embodiment.

When an external force is applied to member 38 from the top as indicated by an arrow in Fig. 5, substrate 11 deforms. At this time, the external force is applied to end 38A of member 38. On the other hand, a reaction force acts to end 28A of member 28 and end 35A of member 35. A tensile stress is also applied to elements 16 and 21, increasing resistance of elements 16 and 21. On the other hand, a compression stress is applied to elements 17 and 23, reducing resistance of elements 17 and 23. Since a bridge circuit is formed among elements 16, 17, 21, and 23, IC 24 outputs a potential difference between first output electrode 19 and second output electrode 20 as the differential voltage through connector 25.

Here, the reaction force applied to member 28 includes a vector which rotates member 28 circumferentially, and thus it is conceivable that member 28 is rotated. However, as shown in Fig. 3, washer 29 has contact head 31 which touches the top face of substrate 11. In addition, washer 30 has contact head 33 which touches the bottom face of substrate 11. These contact heads 31 and 33 may be round. Accordingly, even though washer 29 rotates on the top face and washer 30 rotates on the bottom face of substrate 11 respectively in a circumferential direction, the positions of contact heads against substrate 11 do not deviate lengthwise on substrate 11 with respect to washers 29 and 30. Therefore, a bending stress applied to element 21 provided near member 28 does not change, allowing the strain sensor to maintain stable output characteristic.

In the exemplary embodiment, all washers are made of metal of high mechanical strength. However, the washers can be made of other materials with high mechanical strength, such as ceramics.

In the exemplary embodiment, the detection member is fixed to detection hole 14 so as to fix the detection member to the portion where strain is generated in the measurement target. However, if a member for fixing substrate 11 and the measurement target are provided separately, such as the case of a load cell, a structure that applies a force directly to a position equivalent to detection hole 14 on substrate 11, without providing detection hole 14 and the detection member, ~~is also applicable~~ would also be functional and is considered within the scope of the present invention.

In the exemplary embodiment, two fixing holes are provided. However, one fixing hole is acceptable, depending on the structural design of attachment.

## INDUSTRIAL APPLICABILITY

In the present invention, each fixing member is composed of an upper washer and a lower washer, and these upper and lower washers sandwich and hold a sensor substrate. Accordingly, the fixing member is fixed onto the sensor substrate. The fixing member is secured to the sensor substrate using a force perpendicular to the thickness direction of the sensor substrate, which is produced by sandwiching the sensor substrate with the upper washer and lower washer. This eliminates any internal stress produced by twisting around the fixing hole on the sensor substrate; no stress thus is continuously applied to the strain-detecting element. As a result, the present invention offers a strain sensor that generates an accurate output signal.

**ABSTRACT**

A fixing member is composed of an upper washer and a lower washer; and a sensor substrate is sandwiched and held ~~with these~~ by the upper and lower washers. A strain-detecting element is disposed on the sensor substrate. A strain sensor as  
5 configured above is fixed onto a measurement target via the fixing member. Accordingly, the strain sensor does not generate an output signal when no external force is applied, demonstrating stable characteristics.
